Abstract--

Historical maps, archives, genealogies, and oral history indicate at least four (4) sites in North Carolina’s Dare (2), Hyde (1) and Tyrrell (1) Counties as Native settlements. One or more of these sites may have provided sanctuary for refugees from the ill-fated colony established on Roanoke Island in 1587.

The archaeological research design of the Lost Colony Center for Science and Research consists of a predictive model using traditional data but also remote sensing applications, that is, aerial, satellite and geophysical. Environmental studies with remote sensing assist in confirming the sites as habitable. Optical imagery and processing provided the initial results about the locales being habitable (2003 URE Lost Colony Team).

Prior study of high-resolution satellite imagery of the Buckridge site in Tyrrell County identified environmental characteristics conducive to habitation. The ridge vegetation of mixed trees was distinct compared to the surrounding wetlands. However, at the highest available spatial resolution (1m) the vegetative canopy obscured the ground at these sites. This study also did not address other factors related to habitation.

The current study correlates remote sensing imagery with historical geospatial information to evaluate the suitability for settlement at three locales. For this study, settlement suitability is based upon observable, interdependent, quantifiable environmental factors governing habitability (settlement size and area), arability (soils and vegetation) and defensibility (geographical location and elevation). To determine these factors, data from satellite based Optical and ISAR instruments and aerial LIDAR are compared to observe and quantify the terrain and environment of the historical locales.

Interferometric Synthetic Aperture RADAR (ISAR) data allows penetration of obscuring vegetative canopies, although at a spatial resolution (30 m.) insufficient to detect discrete cultural features. Light Detection and Ranging (LIDAR) data provides adequate spatial resolution (<1 m.) but is subject to statistical uncertainties over small areas.

For this study, ISAR data from NASA’s Shuttle RADAR Topography Mission and LIDAR data from the North Carolina Floodplain Mapping Program were compared to improve the site elevation accuracy. The use of new, public, environmental data sets provided the opportunity to refine the requisite settlement characteristics of habitability, arability and defensibility. The proximate location of sites to ECSU yielded an opportunity to establish ground truth for measurements made remotely. Once remote elevation and environmental data are validated, each site will be the focus of further in-situ study to confirm settlement characteristics.

The study continues with Geophysical applications, especially Ground Penetrating Radar, and geologic core samples at the sites with the requisite environmental and terrain characteristics. The 2005 URE project initiated this in situ study at Croatan (Dare) and at Goshen Ridge (Hyde).

I. INTRODUCTION

A. Background

In 1587, a group of about 117 colonists made a voyage from England to settle in the new land and attempt to seize one of the infinite possibilities of starting a new way of life. With this drastic jump into the depths of the unknown came many sacrifices. As time went on, resources became scarce and the colonists were in need of a representative to go back to England to obtain the materials needed for survival. It is recorded that they sent John White, governor of the colony, to England to retrieve the much needed supplies. Upon his
Archaeological studies. The combination of archeology and be able to utilize these advancements as an aide in that occur in the field of science everyday, we are fortunate to assist in our progression. With the technological advances archeological investigations and used modern day technology accomplished by several means including visual detection of archaeological sites may be C. Remote Sensing in Archeology Detection of archaeological sites may be accomplished by several means including visual aerial reconnaissance and the use of remote sensors as aerial cameras, thermal infrared scanners, multispectral scanners, and space-borne radar. Remote sensing has proven to be useful in locating both surface and subsurface archaeological features. Much of human history can be traced through the impacts of human actions upon the environment. The use of remote sensing technology offers the archeologist the opportunity to detect these impacts which are often invisible to the naked eye.

Trying to locate archaeological sites is limited by several factors. Number one, it has to be small enough to be seen and comprehended from visible remains. Second, it has to be recognizable and visible in spite of subsequent human activities and constructions. Third, long exposure to the effects of nature, such as weathering and erosion should not make it unrecognizable.

Remote Sensing can overcome these limitations. Very large sites can only be seen in its entirety. Patterns of sites that may not be noticed or understood at ground level may be viewed at another perspective. Subtle variations in the soil color, in the density, height, or types of vegetations, or patterns of shadows may give suggestions to the underlying buried features.

We used a few types of remote sensing imagery in our research. Light Detection And Ranging (LIDAR) operates at optical wavelength. Radio Detection And Ranging (RADAR) operates at Radio wavelengths (1 cm - 1 m). Ground Penetrating Radar detects inconsistencies underground (1 ft – 30 ft). The Shuttle Radar Topography Mission displays topographic imagery. We also used imagery from the IKONOS satellite.

II. METHODOLOGY

A. Hypothesis
We will compare and contrast the different imagery we obtain from the different remote sensing applications. The colonists removed to sites associated with Native American habitation and characterized by agricultural suitability, defensibility, sufficient settlement size, economic Prospects and whether they were within support range of Native American allies (Croatan). Sites near Buxton on Cape Hatteras and near the Alligator River headwaters may conform to colonist proposed settlement requirements.

B. Approach
Locate remnant features indicating the location of the “Lost Colony” using an amalgam of remote sensing data processing and GIS techniques. Data: Optical imagery, LIDAR, ISA-RADAR, GPR. GIS Technology: GPS. The archeological methodology will include historical map comparison to locate known sites.

The lost colony research team from summer 2003 examined IKONOS data. To continue the quest for information about the migration of the colonists, additional data was collected and analyzed. First, PG-Steamer was used to manipulate IKONOS data. The data enabled the team to focus in on optical data of one of the sites that the team would later visit. Buck Ridge appeared to have vegetation and levels of elevation at certain parts; this was confirmed by visiting the location.

C. Site Validation
Using remote sensing applications such as LIDAR and SRTM, we are able to distinguish the height differentiation between natural land features. With the retrieval of this data, we can evaluate the possible places the “Lost Colony” can be located. The data we possess shows the relevance to “Lost
“Lost Colony” studies because the fort would have been built on a ridge to escape flooding and for defensibility. This factor gives us a reason to assume that Buck Ridge, Goshen Ridge, and Buxton are possible sites where the “Lost Colony” could have migrated. Added to the fact that John White has documented writings saying the colonists were prepared to move 50 miles into the mainland. The area of Goshen Ridge (fig. 1) is approximately 50 miles from Roanoke Island.

The Alligators River has changed tremendously from 1585 to present and will still alter due to weather and other natural and environmental changes.

III. RESULTS

In the duration of our research we have tabulated outcomes displaying elevation, distance, and area measurements using locations off the Eastern Coastal Shores of North Carolina pertaining to IKONOS, LIDAR and SRTM satellite images. The chart above shows various calculations of Croatan (Dare County), Goshen Ridge (Hyde County) and Buck Ridge (Tyrrell). The figure above show a variety of elevations, distances, and areas at potential brumes. Berms on the IKONOS elevation chart indications range from dark green and grey to a purplish grey color. LIDAR indications range from dark orange to white, and SRTM indications range from light grey to white. The following assumptions articulate the locations of North Carolina Coastal berms along with precise elevation, distance, and area measurements.

IV. DISCUSSION

Our recommendations for future studies consist of historical map (GIS) study, airborne ISAR data, and Ground Penetrating Radar data. After the imagery study, we must also go to the sites in question and ground-truth the area, evaluate via archaeological survey, study living descendants, and also research other possible locations.

V. ACKNOWLEDGMENT

Special thanks to our mentors, Dr. Anne Garland, Dr. Malcolm Lecompte, Dr. Francisco San Juan, Mr. Fred Willard and Dr. Lei Zhang. Many thanks to Dr. Linda Hayden and the entire CERSER and URE-OMSS staff for a wonderful internship experience.
